PAPER

Please find below and/or attached an Office communication concerning this application or proceeding.

The time period for reply, if any, is set in the attached communication.

Office Action Summary	Application No. 10/674,131	Applicant(s) COMERFORD ET AL.	
	Examiner NATALIE LENNOX	Art Unit 2626	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

- 1) ☒ Responsive to communication(s) filed on 04 January 2008.
- 2a) ☐ This action is **FINAL**. 2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

- 4) ☒ Claim(s) 1-22 and 26-31 is/are pending in the application.
- 4a) Of the above claim(s) _____ is/are withdrawn from consideration.
- 5) ☐ Claim(s) _____ is/are allowed.
- 6) ☒ Claim(s) 1-22 and 26-31 is/are rejected.
- 7) ☐ Claim(s) _____ is/are objected to.
- 8) ☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on _____ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some * c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
 2. ☐ Certified copies of the priority documents have been received in Application No. _____.
 3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

This Office Action has been issued in response to the Pre-Appeal Brief filed January 4, 2008.

Applicant's request for reconsideration of the finality of the rejection of the last Office action is persuasive and, therefore, the finality of that action is withdrawn.

Claim Rejections - 35 USC § 103

1. The text of those sections of Title 35, U.S. Code not included in this action can be found in a prior Office action.
2. Claims 1, 6, 9, 14-15, 18-19, 20, 22, and 27 are rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497) in view of Petajan (US Patent 4,975,960), and in further view of Paterson et al. (US Patent 5,794,163), hereinafter Paterson.

As per claim 1, Marshall teaches an apparatus for imaging the mouth of a user while detecting the speech of the user comprising:

a headset adapted so as to be worn on the head of the user (Fig. 1, headset 100 and Fig. 3);

a microphone mounted on the headset and positioned so as to detect the speech of the user (Fig. 1, microphone 104 and Fig. 3);

an illumination source mounted on the headset for illuminating the mouth of the user (component 102 of Fig. 1, also in Col. 3, lines 43-47, a user headset 100 is shown to be provided with a combination of photodetectors and/or thermal detectors 102 with

the former of these being also provided with a light emitting diode source of optical illumination energy);

a photodetector mounted on the headset and positioned so as to capture a frontal view of the mouth of a user (photo/thermal detector(s) from Fig. 3, also Col. 3, lines 42-45, In this Fig. 1 embodiment of the invention, a user headset 100 is shown to be provided with a combination of photodetectors and/or thermal detectors 102);

a communication device transmitting the output of the photodetector and the output of the microphone to a computer (Col. 3, lines 48-51, all of these energy transducers provide electrical signals to an analog signal processing apparatus 106 (from Fig. 1) by way of the multiple channeled flexible tether cord 118).

However, Marshall does not specifically mention that the photodetector is a video camera. Petajan teaches a solid state video camera (Col. 5, line 7), which has an image sensor array less than four square centimeters in area, and which could conceivably be head mounted beside a microphone and light sources on a boom (Col. 5, lines 20-23). Petajan also shows in Fig. 7 that camera 20 is located in front of the user and from Figs. 1 and 2 we clearly see that the image obtained from the camera shows the frontal area of the mouth.

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a video camera mounted on a headset as taught by Petajan for Marshall's apparatus because Petajan provides an apparatus and method for electronically tracking and detecting facial features and apparatus and methods for automatic speech recognition (Col. 1, lines 10-13), wherein the tracking

Art Unit: 2626

system is used for speech recognition (Col. 2, lines 31-32) and wherein the invention uses a video camera to scan the individual's face (Col. 2, lines 20-21).

Also, Marshall and Petajan do not specifically mention the apparatus comprising:
a speaker for transmitting sound to the user, the speaker positioned in proximity to the ear of the user;

a communication path from the computer to the speaker;
wherein the communication device for communicating the output of the microphone to the computer and communication path from the computer to the speaker are used in combination to perform conventional telephony wherein the computer communicates with telephony interfaces.

However, Paterson teach
a speaker for transmitting sound to the user, the speaker positioned in proximity to the ear of the user (Col. 8, lines 12-33, with headset 102, earphone capsule 204, headset speaker 116);

a communication path from the computer to the speaker (Col. 4, line 62 to Col. 5, line 1, also Col. 4, lines 5-10);

wherein the communication device for communicating the output of the microphone to the computer and communication path from the computer to the speaker are used in combination to perform conventional telephony wherein the computer communicates with telephony interfaces (Col. 4, lines 42-44, Col. 8, lines 13-14, and Col. 8, lines 26-27).

Paterson also teaches the known technique of using a speaker which is placed within the headset for receiving audio in a communication device that performs telephony functions. A person of ordinary skill in the art would have recognized that applying the known technique of a speaker within a headset placed in proximity to a user's ear and which is connected to a communication device would have yielded predictable results and would have improved the headset and computer functions of Marshall and Petajan. Therefore, it would have been obvious to a person having ordinary skill in the art at the time of invention to apply Paterson's known technique of a speaker into Marshall's headset, as modified by Petajan, in order to permit the user to receive audio from the computer.

Marshall, in view of Petajan, teaches a headset with a video camera, microphone, and an illumination source mounted on the headset, where the output of the video camera and the output of the microphone are transmitted to a computer. Paterson teaches a headset with a microphone and a speaker positioned in proximity to the ear of a user and a communication path from a wireless phone to the speaker, where the output of the microphone to the wireless phone and from the wireless phone to the speaker are used in combination to perform conventional telephony. Since each individual element and its function, as described in claim 1, are shown in the prior art, albeit shown in separate references, the difference between the claimed subject matter and that of the prior art rests not on any individual element or function but in the very combination itself; that is, in the substitution of Paterson's wireless phone for Marshall's computer. It would have been obvious to a person having ordinary skill in the art to

make this substitution in order to improve the computer functions of Marshall and Petajan by allowing it to perform conventional telephony as provided by Paterson.

As per claim 6, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the video camera is positioned so as to capture a frontal view of the mouth of the user and is positioned substantially on the center line of the mouth (Petajan's Fig. 7 shows that the video camera is positioned in front of the user and, as shown on Fig. 2, it is capturing a frontal view of the mouth. Also Marshall's Fig. 3, shows the photo/thermal detectors attached to the headset and placed in front of the mouth of the user.).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of the video camera positioned so as to capture a frontal view of the mouth of the user and positioned substantially on the center line of the mouth as taught by Petajan for Marshall's apparatus because Petajan provides an apparatus and method for electronically tracking and detecting facial features and apparatus and methods for automatic speech recognition (Col. 1, lines 10-13), wherein the tracking system is used for speech recognition (Col. 2, lines 31-32) and wherein the invention uses a video camera to scan the individual's face (Col. 2, lines 20-21).

As per claim 9, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the microphone is of the noise reduction type

(Paterson's Col. 8, lines 45-48 and Fig. 2, also Col. 8, lines 55-63).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a microphone of noise reduction type as taught by Paterson for Marshall's apparatus, as modified by Petajan, because Paterson provides a variety of circuit elements in both wireless telephone 101 and in headset 102 to suppress noise caused by the TDD/TDMA RF environment (Col. 7 line 67 to Col. 8 line 3).

As per claim 14, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the illumination source is continuously energized (Marshall's Col. 4, lines 60-63, either the battery operated light emitting diode arrangement or the pulsating energy source energized light emitting diode may be used in the Fig. 1 and Fig. 2 embodiments of the present invention).

As per claim 15, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the illumination source being periodically energized (Marshall's Col. 4, lines 60-63, either the battery operated light emitting diode arrangement or the pulsating energy source energized light emitting diode may be used in the Fig. 1 and Fig. 2 embodiments of the present invention).

As per claim 18, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the headset includes a boom supporting the video camera

and illumination source so as to capture the frontal view of a mouth (Marshall's Fig. 3 shows the headset with a boom attached to it holding the photo/thermal detector(s) and LED, also Petajan's Col. 5, lines 20-23, since the image sensor array less than four square centimeters in area, it could conceivably be head mounted beside a microphone and light sources on a boom).

As per claim 19, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 18, wherein the boom supports the microphone in the vicinity of the mouth (Marshall's Fig. 3 shows the headset with the microphone attached to the boom and near the mouth).

As per claim 20, Marshall, in view of Petajan and Paterson, teach the apparatus of claim 1, further comprising an amplifier coupled to the microphone (Paterson's Col. 8, lines 26-27).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of an amplifier coupled to a microphone as taught by Paterson for Marshall's apparatus, as modified by Petajan, because Paterson provides a headset for hands-free wireless telephone, where the headset includes an earphone capsule (Col. 8, lines 13-14), and wherein the earphone capsule includes an amplifying circuitry for amplifying the weak signal from the microphone (Col. 8, lines 26-27).

As per claim 22, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, wherein the communication device is cabling (Marshall's Fig. 1 and Col. 3, lines 48-51, all of these energy transducers provide electrical signals to an analog signal processing apparatus 106 by way of the multiple channeled flexible tether cord 118).

As per claim 27, Marshall, in view of Petajan and Paterson, teach the apparatus of claim 1 further comprising:

a speaker for transmitting sound to the user, the speaker positioned in proximity to the ear of the user (Paterson's Col. 8, lines 12-33, with headset 102, earphone capsule 204, headset speaker 116);

a wireless telephony transceiver connected to the speaker and the microphone to provide wireless telephony functions (Paterson's Col. 4, lines 59-66).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the features of a speaker and a wireless telephony transceiver as taught by Paterson for Marshall's apparatus, as modified by Petajan, because Paterson provides a portable telephone having a headset allowing hands-free operation of the portable telephone in a time division duplex (TDD) or time division multiple access (TDMA) communication system (Col. 1, lines 10-14).

1. Claims 2-5 are rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent

4,975,960) and further in view of Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Cofer et al. (US 2002/0061134), hereinafter Cofer.

As per claim 2, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the video camera being a black and white CMOS type camera. However, Cofer teaches an image capturing device, preferably a standard black and white CCD video camera 810 (from Fig. 18) operating at thirty frames per second, [and wherein the] use of a color or CMOS-based camera is also contemplated (Paragraph 0103]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a black and white CMOS type camera as taught by Cofer for Marshall's apparatus, as modified by Petajan and Paterson, because Cofer provides a visual object detection system that uses one or more images from a video camera, digital camera, etc., to provide access and/or presence monitoring of an area of interest (paragraph [0008]).

As per claim 3, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the video camera being a color CMOS type camera. However, Cofer teaches an image capturing device, preferably a standard black and white CCD video camera 810 (from Fig. 18) operating at thirty frames per second, [and wherein the] use of a color or CMOS-based camera is also contemplated (Paragraph 0103]).

It would have been obvious to one having ordinary skill in the art at the time the

invention was made to have used the feature of a color CMOS type camera as taught by Cofer for Marshall's apparatus, as modified by Petajan and Paterson, because Cofer provides a visual object detection system that uses one or more images from a video camera, digital camera, etc., to provide access and/or presence monitoring of an area of interest (paragraph [0008]).

As per claim 4, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the video camera being a black and white CCD type camera. However, Cofer teaches an image capturing device, preferably a standard black and white CCD video camera 810 (from Fig. 18) operating at thirty frames per second, [and wherein the] use of a color or CMOS-based camera is also contemplated (Paragraph 0103]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a black and white CCD type camera as taught by Cofer for Marshall's apparatus, as modified by Petajan and Paterson, because Cofer provides a visual object detection system that uses one or more images from a video camera, digital camera, etc., to provide access and/or presence monitoring of an area of interest (paragraph [0008]).

As per claim 5, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the video camera being a color CCD type camera. However, Cofer teaches an image capturing device, preferably a

standard black and white CCD video camera 810 (from Fig. 18) operating at thirty frames per second, [and wherein the] use of a color or CMOS-based camera is also contemplated (Paragraph 0103)).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a color CCD type camera as taught by Cofer for Marshall's apparatus, as modified by Petajan and Paterson, because Cofer provides a visual object detection system that uses one or more images from a video camera, digital camera, etc., to provide access and/or presence monitoring of an area of interest (Paragraph [0008]).

2. Claims 7, 29, and 30 are rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Lahr (US 2002/0194005).

As per claim 7, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the video camera positioned so as to capture a frontal view of the mouth of the user and is positioned to the side of the center line of the mouth. However, Lahr teaches a first camera pointing toward the lips, mounted at a nearly central location on the side of the pivoting bail band closest to the lips so as to provide a frontal lip camera function (Paragraph [0023] and Fig. 6b).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a video camera positioned to the side of

the center line of the mouth as taught by Lahr for Marshall's apparatus, as modified by Petajan and Paterson, because Lahr provides a head-worn, tri-modal device for increasing transcription accuracy in a voice recognition process and/or for processing unvocalized speech (Paragraph [0002]). Lahr also provides that a form of machine lip reading using camera data take place to augment the analog voice recognition processing. The data obtained from the machine lip reading would serve as additional input "decision base" channels to aid the algorithmic processors to convert the spoken speech into written words (Paragraph [0095]). The actual lip reading would utilize one or more cameras mounted adjacent to the speaker's lips. As shown in Fig. 6 and 7, three cameras may be used (Paragraph [0096]).

As per claim 29, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the apparatus further comprising a fiber optic cable providing an optical image of the frontal view of the mouth to the video camera. However, Lahr teaches that should the desired camera be somewhat large for the desired bail arm shape, it is also possible to mount the cameras near the pivot point of the bail arm, and use an imaging fiber optic cable to transfer the optical image from the pickup point on the bail arm to the light sensitive chip in the camera circuit (Paragraph [0091]), wherein the pickup points on the bail arm are where the cameras are located and according to paragraph [0090] there are two frontal cameras (one anamorphic camera that looks at the whole mouth, and a center detail

camera that looks just at the middle quarter of the mouth), and a side camera (looking at just lip protrusion, as in lip pursing).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a fiber optic cable providing an optical image of the frontal view of the mouth to the video camera as taught by Lahr for Marshall's apparatus, as modified by Petajan and Paterson, because Lahr provides a head-worn, tri- modal device for increasing transcription accuracy in a voice recognition process and/or for processing unvocalized speech (Paragraph [0002]), also he provides the use of plastic fibers in a fiber optic cable in order to substantially reduce costs (Paragraph [0091]).

As per claim 30, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the illumination source including a fiber optic cable to illuminate the mouth of the user. However, Lahr teaches that with modern optical processors, it is even possible to utilize fiber cables that were not collated in their manufacture (as in illumination fiber cables) by "collating" the output of each fiber by a new data address (Paragraph [0091]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a fiber optic cable providing an optical image of the frontal view of the mouth to the video camera as taught by Lahr for Marshall's apparatus, as modified by Petajan and Paterson, because Lahr provides a head-worn, tri- modal device for increasing transcription accuracy in a voice recognition

process and/or for processing unvocalized speech (Paragraph [0002]), also he provides the use of plastic fibers in a fiber optic cable in order to substantially reduce costs (Paragraph [0091]).

3. Claim 8 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Harman (US Patent 6,473,115).

As per claim 8, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the apparatus further comprising an optical filter limiting light entering the video camera to a band of infrared wavelengths. However, Harman teaches a video camera used in the tracking means (2), that may be a CCD or vidicon type, the lens of which is fitted with an infrared bandpass filter (Col. 5, lines 38-39, and tracking means (2) from Figs. 1a & 1b).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a video camera with an infrared filter as taught by Harman for Marshall's apparatus, as modified by Petajan and Paterson, because Harman provides a multiple viewer image viewing system capable of providing a plurality of images to viewers and/or a three dimensional (3D) visual effect in a viewed image (Col. 1, lines 9-12).

4. Claims 10-13 are rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Jones, II et al. (US 2005/0178841), hereinafter Jones.

As per claim 10, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the illumination source including a plurality of broadband light emitters. However, Jones teaches a light source 10 that provides optical excitation for the mark (targeted object), which may consist of a pulsed Xe strobe or flashlamp, a broadband source such as a halogen lamp or incandescent, a chopped broadband or discrete source such as a laser, LED or super-luminescent LED, a time-modulated broadband source or discrete source, etc. The source can consist of one or more of these optical sources; for example, it might incorporate several narrow- band LEDs to excite a variety of luminescent compounds (Paragraph [0061]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of an illumination source including a plurality of broadband light emitters as taught by Jones for Marshall's apparatus, as modified by Petajan and Paterson, because Jones provides a method and system whereby products or documents can be identified based on the recording of a luminescent image. The image consists of a discrete luminescence spectrum and a well defined luminescence decay time. Using a pulsed source for photoexcitation, luminescence intensities are recorded as a function of time following initiating pulses of

light. Wavelength and time resolution of luminescence signals produces a unique signature that can be identified with a particular product or document (Paragraph [0048]).

As per claim 11, Marshall, as modified by Petajan and Paterson, and further in view of Jones, teach the apparatus according to claim 10, further comprising an optical filter limiting light emitted from said broadband light emitters to a band of infrared wavelengths (Jones's emission filter of Fig. 11 and paragraph [0067], The Emission Filter 6 shapes the optical emission spectrum of the excited Mark (targeted object). It can consist of a grating, a dielectric filter or stack, a short-pass filter, a band- pass filter, a line filter to filter out ambient light, a glass filter, or any other optical spectrum-shaping element. The Emission Filter may incorporate several of these filters, for example in a filter wheel The Emission Filter may pass spectral power in the emission wavelength bands of the Mark luminescence. The Emission Filter may pass wavelengths in some subset(s) of the UV, visible, and infrared portions of the spectrum).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of an optical filter limiting light emitted from said broadband light emitters to a band of infrared wavelengths as taught by Jones for Marshall's apparatus, as modified by Petajan and Paterson, because Jones provides a method and system whereby products or documents can be identified based on the recording of a luminescent image. The image consists of a discrete luminescence spectrum and a well defined luminescence decay time. Using a pulsed source for

Art Unit: 2626

photoexcitation, luminescence intensities are recorded as a function of time following initiating pulses of light. Wavelength and time resolution of luminescence signals produces a unique signature that can be identified with a particular product or document (Paragraph [0048]).

As per claim 12, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the illumination source including a plurality of narrowband light emitters. However, Jones teaches a light source 10 that provides optical excitation for the mark (targeted object), which may consist of a pulsed Xe strobe or flashlamp, a broadband source such as a halogen lamp or incandescent, a chopped broadband or discrete source such as a laser, LED or super-luminescent LED, a time-modulated broadband source or discrete source, etc. The source can consist of one or more of these optical sources; for example, it might incorporate several narrow-band LEDs to excite a variety of luminescent compounds (Paragraph [0061]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of the illumination source including a plurality of narrowband light emitters as taught by Jones for Marshall's apparatus, as modified by Petajan and Paterson, because Jones provides a method and system whereby products or documents can be identified based on the recording of a luminescent image. The image consists of a discrete luminescence spectrum and a well defined luminescence decay time. Using a pulsed source for photoexcitation,

luminescence intensities are recorded as a function of time following initiating pulses of light. Wavelength and time resolution of luminescence signals produces a unique signature that can be identified with a particular product or document (Paragraph [0048]).

As per claim 13, Marshall, as modified by Petajan and Paterson, and further in view of Jones, teach the apparatus according to claim 12, further comprising an optical filter limiting light emitted from said narrowband light emitters to a band of infrared wavelengths (Jones's emission filter of Fig. 11 and paragraph [0067], The Emission Filter 6 shapes the optical emission spectrum of the excited Mark (targeted object). It can consist of a grating, a dielectric filter or stack, a short-pass filter, a band- pass filter, a line filter to filter out ambient light, a glass filter, or any other optical spectrum-shaping element. The Emission Filter may incorporate several of these filters, for example in a filter wheel The Emission Filter may pass spectral power in the emission wavelength bands of the Mark luminescence. The Emission Filter may pass wavelengths in some subset(s) of the UV, visible, and infrared portions of the spectrum).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of an optical filter limiting light emitted from said narrowband light emitters to a band of infrared wavelengths as taught by Jones for Marshall's apparatus, as modified by Petajan and Paterson, because Jones provides a method and system whereby products or documents can be identified based on the recording of a luminescent image. The image consists of a discrete

luminescence spectrum and a well defined luminescence decay time. Using a pulsed source for photoexcitation, luminescence intensities are recorded as a function of time following initiating pulses of light. Wavelength and time resolution of luminescence signals produces a unique signature that can be identified with a particular product or document (Paragraph [0048]).

5. Claim 16 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 15 above, and further in view of Tomioka (US Patent 6,803,947).

As per claim 16, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 15, but they do not specifically mention the illumination source being de-energized during retrace or blanking periods of the video camera. However, Tomioka teaches a video camera and the process of acquisition of a still picture by the video camera (Col. 3, line 66), wherein during the acquisition preparations, the CCD driver 9 generates first and second readout signals (B1 and B2) in synchronization with alternate vertical synchronization signals (A), but the strobe lamp is turned off, the subject is not illuminated, substantially no charge accumulates in the sensor elements, and the output video signal (D) is black. The external device that controls the strobe lamp drives the strobe timing signal high for a brief interval between two consecutive vertical synchronization signals (A), not overlapping either readout signal (B 1, B2). When strobe light goes high, accordingly, the strobe lamp generates a flash of light that

illuminates the subject during the integration time of the sensor elements in the CCD image sensor²; that is, during the time in which the sensor elements accumulate charge. Light reflected from the subject is focused by the lens 1 onto the CCD image sensor², producing photocharges in proportion to the incident light intensity (Fig. 4 and Col. 4, lines 6-23).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of de-energizing illumination source during retrace or blanking periods of the video camera as taught by Tomioka for Marshall's apparatus, as modified by Petajan and Paterson, because Tomioka provides a video camera that generates a video signal by mixed-line-pair readout from a solid-state image sensor with a complementary color filter (Col. 1, lines 7-9). Also Tomioka provides a video camera that can take still pictures in color with full vertical resolution, equivalent to the pictures taken by an electronic still camera, and a method for obtaining full-resolution still pictures from a solid-state image sensor and signal processing circuits of the type normally used to generate color moving pictures with interlaced scanning (Col. 2, lines 43-50).

6. Claim 17 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 15 above, and further in view of Rubis (US Patent 3,771,038).

As per claim 17, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 15, but they do not specifically mention the illumination source being periodically energized by a pulse generator having a pulsed output, wherein a period of the pulsed output and a pulse width of the pulsed output are independently controlled. However, Rubis teaches a pulse generator 47 having an adjustable period, which is the sampling period T. The output of pulse generator 47 is a pulse waveform having the period T (Col. 3, lines 25-27). Rubis also teaches a pulse stretcher 49 connected to receive the output of the pulse generator 47, and is adjusted to stretch the width of the pulse generated waveform to a value (Col. 3, lines 38-41).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of an independently controlled period of a pulse output and pulse width of pulsed output as taught by Rubis for Marshall's apparatus, as modified by Petajan and Paterson, because Rubis provides a pulse output amplifier with an adjustable period and adjustable pulse width sampling time [...]. The sampling period and sampling time is made adjustable for use with various kind of electronic or electromechanical systems where the sampling period or sampling time may be made necessarily short or long in accordance with utilization needs of the device (Col. 2, lines 10-18).

7. Claim 21 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960)

and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Bridgelall (US 2003/0110508).

As per claim 21, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the communication device including a radio frequency transmitter receiving the video output of the video camera and the audio output of the microphone and a corresponding receiver adapted to provide the video and audio to the computer. However, Bridgelall teaches a dual radio frequency (RF) transceiver and an audio video data processor both supported on a common support having a predetermined form factor. Each RF transceiver is operative for communicating with a computer network, through different communication channels such as (i) a wireless LAN, and (ii) a WAN, GPRS, CDPD, or GSM cellular telephone network (Paragraph [0023], also from Fig. 1, wireless data RF transceiver antennas 21, 22, and 23, also video input 12 and microphone (not numbered but shown as part of subassembly 11)).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a radio frequency transmitter as taught by Bridgelall for Marshall's apparatus, as modified by Petajan and Paterson, because Bridgelall provides a single integrated module including distinct RF transceivers and optionally an interface to a video camera, or auto ID reader, all mounted on a common support, especially on a standard form factor such as a compact flash card for use in mobile computers (Paragraph [0020]).

8. Claim 26 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Lewis et al. (US 2003/0167169), hereinafter Lewis.

As per claim 26, Marshall, as modified by Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the computer being adapted to perform telephony functions over the internet. However, Lewis teach a speech recognition system 100 (SRS) that interacts with a user 105 to access any of a variety of speech-enabled applications or speech-based functions. The speech recognition engine 115, the TTS 120, the SRS data 125, as well as the audio interface 110 of the SRS 100 can be implemented within a computer system having suitable audio processing circuitry or a "sound card." Once a voice link has been established between the user 105 and the SRS 100, an enrollment script can be played to the user through the audio interface 110. For example, the enrollment script can be played from the computer system through a microphone/headset operatively connected to the computer system or from the computer system through a communications network such as the Internet or the public switched telephone network (PSTN), in which case the audio interface can be a telephone handset, headset, mobile phone, or the like (Paragraph [0020]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a computer adapted to perform telephony functions over the internet as taught by Lewis for Marshall's apparatus, as

modified by Petajan and Paterson because Lewis provides a nonvisual method of enrolling users in a speech recognition system (SRS) [...] through an audio interface (Paragraph [0014]), wherein the audio interface can be a microphone/headset combination or a telephone handset or headset (Paragraph [0019]).

9. Claim 28 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Neal et al. (US Patent 6,547,395), hereinafter Neal.

As per claim 28, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the illumination source being adjustable to shape a light output distribution to reduce exposure of eyes of the user to the light output. However, Neal teach a system using a pulsed wavefront sensor to measure the human eye while reducing the total exposure by controlling the duty cycle of the pulsed light source (Fig. 4 and Col. 3, lines 51-54).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of adjustable illumination source as taught by Neal for Marshall's apparatus, as modified by Petajan and Paterson, because Neil provides way to use pulsed wavefront sensors for applications in addition to measurement of pulsed lasers. In particular, [...] to using a pulsed wavefront sensor to measure moving elements, to simplify measurements involving moving parts, and to reduce exposure, particularly for use with biological systems (Col. 1, lines 27-33).

10. Claim 31 is rejected under 35 U.S.C. 103(a) as being unpatentable over Marshall (US Statutory Invention Registration H1497), in view of Petajan (US Patent 4,975,960) and Paterson (US Patent 5,794,163) as applied to claim 1 above, and further in view of Schneider et al. (US 2003/0198357), hereinafter Schneider.

As per claim 31, Marshall, in view of Petajan and Paterson, teach the apparatus according to claim 1, but they do not specifically mention the apparatus further comprising a tube acoustically coupled to the microphone so as to provide speech of the user to the microphone. However, Schneider teaches a Signal Intelligibility Enhancement (SIE) processor (Paragraph [0024]) that includes a second acoustic input device 402 (from Fig. 4) that is typically located either inside the ear canal (a so-called closed-loop implantation) or outside the ear canal (a so-called open-loop implementation) (Paragraph [0038]), wherein the closed-loop implementation may be an acoustic tube that supplies audio to a microphone molded into the ear cup (Paragraph [0039]).

It would have been obvious to one having ordinary skill in the art at the time the invention was made to have used the feature of a tube acoustically coupled to a microphone as taught by Schneider for Marshall's apparatus, as modified by Petajan and Paterson, because Schneider provides a Signal Intelligibility Enhancement (SIE) algorithm that utilizes a measurement of either (1) the level of the outside interference (undesired signal, noise) or (2) the level of the interference (undesired signal, noise) in the headset ear cup or in the ear canal to adaptively adjust the gain and equalization of

the signal-of-interest (electrical) so that the intelligibility and audibility of the signal-of-interest is improved (Paragraph [0015]).

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to NATALIE LENNOX whose telephone number is (571)270-1649. The examiner can normally be reached on Monday to Friday 9:30 am - 7 pm (EST).

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Richemond Dorvil can be reached on (571)272-7602. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
